## Which Operators to Overload Solutions

## Useful Operators to Overload

- Give some examples of operators which are useful to overload
  - Assignment operator =
  - Equality operator ==
  - Inequality operator !=
  - Less than operator <</li>
  - Function call operator ()
- Why is overloading arithmetic operators not generally useful?
  - Most types do not have arithmetic behaviour

## Operators which should not be overloaded

- Why is overloading the logical AND and OR operators (&& and ||) not recommended?
  - The built-in versions of these operators have "short-circuit" evaluation
  - This relies on a guaranteed order of execution
  - For user-defined versions, this guarantee was not available until C++17

## Recommendations

- Why is it good practice to make operators in our classes behave the same way as the corresponding C++ operators?
  - Overloaded operators which behave differently from the C++ ones are confusing to work with
  - This often causes bugs
